You don't often get email from mhuot@mit.edu. [Learn why this is important](#)

Hi Atticus,

Nice to meet you and thanks for your interest in our paper! Your understanding of `closure(e)` is correct, and I think we could have written more clearly to avoid ambiguities. While going from semi-ring to ring-structure naturally extends to dictionary types in our system as indicated, we did not mean to imply the same for the closure operator. Our point was that many additional structure on top of semi-rings can be added and leveraged for specific algorithms and optimizations while keeping the core semi-ring structure around for the general system.

This is interesting as it means you don't necessarily need a perfectly symmetric system (everything is a ring, everything is a Kleene algebra, ...) to have a general system unify and leverage many common optimization patterns. In some sense it's a deliberate decision that even if the base type can have a very complex structure which you might be able to leverage in specific ways, for the general sparse system all you need to remember is the bare semi-ring structure.

TLDR we only meant these closure rules to be typed at base types, and it'll be interesting future work to see how much one can push operators like - for rings and closure for Kleene algebra to the general system and see if it unlocks extra optimizations. That said, if you want to continue in this direction, there are useful relations to exploit beyond the base case. For instance a great one is that if A,B are matrices (so dictionary types in our system) then $\text{closure}(A * I + I * B) = \text{closure}(A) * \text{closure}(B)$, and if you don't materialize the tensor right away, this can unlock further optimizations.

Hope this helps and let us know if you have more questions!

Best,

--

Mathieu
